

# Model Documentation of the Boost Converter

## 1 Nomenclature

### 1.1 Nomenclature for Model Equations

$L$	inductivity of the inductor
$C$	capacity of the capacitor
$R$	resistance of the load
$U_E$	input voltage
$i_L$	current through the inductor
$u_C$	voltage over the capacitor
$d$	duty ratio of the switch

### 1.2 Circuit Diagram

Figure 1: Circuit

## 2 Model Equations

State Vector and Input Vector:

$$\underline{x} = (x_1 \ x_2)^T = (i_L \ u_C)^T$$
$$\underline{u} = d$$

System Equations:

$$\dot{x}_1 = -(1 - u) \frac{1}{L} x_2 + \frac{U_E}{L} \quad (1a)$$

$$\dot{x}_2 = (1 - u) \frac{1}{C} x_1 - \frac{1}{RC} x_2 \quad (1b)$$

Parameters:  $L, C, R, U_E$

Outputs:  $x_2 = u_C$

### 2.1 Assumptions

1. The switching frequency is high enough, to prevent the inductor from fully discharging between charging stages.

## 2.2 Exemplary parameter values

		Symbol	Value
Inductivity	$L$	0.00018	H
Capacity	$C$	$2.0 \cdot 10^{-5}$	F
Resistance	$R$	10	$\Omega$
Input Voltage	$U_E$	24	V

## 3 Derivation and Explanation

Using PWM (puls width modulation), instead of only discrete values  $d \in \{0, 1\}$  representing an *open* or *closed* switch, any value of the interval  $[0, 1]$  can be modeled. This is done by using the averaged values for states and inputs:

$$\bar{d} = \frac{1}{T} \int_t^{t+T} d(\tau) d\tau$$

$$\bar{x}_i = \frac{1}{T} \int_t^{t+T} x_i(\tau) d\tau \quad i = 1, 2$$

with the switching period  $T$ . For  $T \rightarrow 0$ , which is achieved by a high enough switching frequency, an averaged model can be obtained.

## 4 Simulation

Figure 2: Simulation of the boost converter.
